One or more aspects relate, in general, to processing within a computing environment, and in particular, to processing associated with internal branch prediction. Some instruction set architectures (ISAs) (e.g., an IA-32 ISA) provide internal branch prediction. Typically, when a branch is predicted, the target address of the instruction in the mispredicted branch is chosen based on the branch's history, and the instruction is not yet fetched. Processing caches are usually relatively small (e.g., 32, 64, etc., bytes), and accesses to the small size processing caches are relatively common. There may be a large imbalance between the number of cache lines in use in a set of instructions, and the number of cache lines in the processing cache that have been accessed by the set of instructions. Some accesses may be to lines that are already in the cache, or cache lines that are not even in the cache. In some cases, a particular access is to a cache line in an invalidated state (e.g., the cache line is a victim) or a cached value is not actually needed because of a preceding branch misprediction. Pages Thursday, June 21, 2012 PJ's Pick Hi Everyone, How's everyone been? I hope everyone has had a productive week. I have to apologize for not posting up anything new, but I was away last week and it was a busy week. In other news I have a linky party on my page as of today called In The Mail. It's the perfect time to play along. Link up your entries below, enter
